

lymphocytoma cutis (LTC) is a rare, benign, localized form of cutaneous lymphoma. It is characterized by a localized accumulation of lymphocytes in the dermis, forming a nodule or plaque. The lesions are typically painless and slow-growing. They can occur on any part of the body, but are most commonly found on the face and neck. The lesions are usually red or pink and may be slightly raised. They can range in size from a few millimeters to several centimeters. The exact cause of LTC is unknown, but it is thought to be a localized immune response. Treatment options include observation, corticosteroids, and surgical removal. The prognosis is generally good, with most lesions resolving within a few months. However, some lesions may recur or progress to more advanced forms of lymphoma. Therefore, regular follow-up is recommended.
