

LYMPHEDEMA is a condition characterized by a chronic accumulation of lymphatic fluid in the interstitial spaces of the body, leading to swelling (edema) and thickening of the skin. It can affect any part of the body, but is most commonly seen in the arms and legs. The condition is often caused by a blockage or damage to the lymphatic system, which is responsible for draining excess fluid from the tissues. This can be due to a variety of factors, including congenital defects, infections, cancer, and trauma. The swelling is typically non-pitting, meaning that the fluid does not shift easily when pressure is applied. Over time, the skin can become thickened and discolored, and there may be an increased risk of infections and skin ulcers. Treatment options include compression therapy, manual lymphatic drainage, and surgery in severe cases.
