

Prurigo Nodularis (Nodular Prurigo) is also known as nodular prurigo, and may be associated with chronic urticaria, atopic dermatitis, or other allergic conditions. It is characterized by the presence of multiple, raised, red, and inflamed nodules on the skin. The nodules are typically 1-2 cm in diameter and are often surrounded by a halo of redness. The condition is often associated with chronic itching (pruritus) and can be caused by a variety of factors, including allergic reactions, skin trauma, and underlying medical conditions. The nodules are often found on the arms, legs, and buttocks, and can be very itchy and uncomfortable. Treatment options include topical corticosteroids, antihistamines, and in severe cases, systemic corticosteroids or immunosuppressants. The condition can be chronic and may require long-term management.
