

Subacute Cutaneous Lupus Erythematosus (SCLE) is a chronic autoimmune disease that affects the skin. It is characterized by the presence of subacute cutaneous lupus erythematosus (SCLE) lesions, which are red, scaly patches that can appear on the face, arms, and legs. SCLE is often associated with other autoimmune diseases, such as systemic lupus erythematosus (SLE) and Sjögren's syndrome. The exact cause of SCLE is unknown, but it is thought to be related to an abnormal immune response. Treatment typically involves the use of corticosteroids and other immunosuppressive drugs to control the disease and prevent further skin damage.
