

Subacute Cutaneous Lupus Erythematosus (SCLE) is a form of lupus erythematosus characterized by skin lesions that are typically photosensitive and do not involve internal organs. The lesions are often annular or subannular, with a central clearing and a raised, scaly border. They are commonly found on the face, neck, and arms. SCLE is associated with autoantibodies, particularly anti-Ro/SSA and anti-La/SSB. The condition is more common in women and is often associated with Sjogren's syndrome. Treatment typically involves the use of corticosteroids and immunosuppressants, along with strict sun protection.
