

HIDRADENITIS suppurativa is a chronic inflammatory condition of the skin characterized by recurrent abscesses and sinus tracts. It is most commonly found in the axilla, groin, and perianal area. The condition is thought to be caused by a combination of factors, including genetic predisposition, hormonal influences, and local skin factors. The pathogenesis is complex, involving follicular occlusion, bacterial infection (often with methicillin-resistant Staphylococcus aureus), and an exaggerated inflammatory response. Treatment options range from medical management with antibiotics and anti-inflammatory drugs to surgical excision of affected areas. The condition can significantly impact quality of life due to its chronic and recurrent nature.
