

Angular cheilitis is a condition characterized by inflammation and infection at the corners of the mouth. It is often caused by a combination of factors, including nutritional deficiencies (such as iron, vitamin B12, and folate), local factors (such as saliva pooling and skin irritation), and systemic conditions (such as diabetes and immunosuppression). The condition typically presents with redness, swelling, and pain at the corners of the mouth, and may be accompanied by yellowish or white exudate. Treatment involves addressing the underlying cause, maintaining good oral hygiene, and using topical antifungal or antibiotic medications.
