

Porokeratosis actinica (PKA) is a rare, chronic, progressive skin condition characterized by the presence of multiple, well-defined, annular, hyperkeratotic skin lesions. These lesions are typically located on sun-exposed areas such as the face, neck, and dorsal hands. PKA is often associated with other cutaneous conditions, including epidermal nevi and seborrheic keratoses. Treatment options include topical corticosteroids, calcineurin inhibitors, cryotherapy, laser vaporization, and photodynamic therapy. The exact cause of PKA is unknown, but it is believed to be related to genetic factors and environmental factors like UV exposure.
