

Seborrheic dermatitis is a common skin condition that causes red, itchy, and scaly patches on the skin. It is caused by an overgrowth of a yeast called Malassezia, which is normally found on the skin. The condition is most common on the scalp, face, and chest, but it can also affect other parts of the body. The symptoms of seborrheic dermatitis include redness, itching, and flaking of the skin. The condition is usually treated with topical antifungal medications and corticosteroids. In severe cases, oral medications may be prescribed. Seborrheic dermatitis is a chronic condition, meaning it can come and go over time. However, with proper treatment, the symptoms can be managed and the skin can return to its normal state.
