

Tinea Pedis and Tinea Cruris are the most common types of tinea. Tinea pedis is a fungal infection of the foot, often caused by Trichophyton rubrum. It is characterized by redness, itching, and scaling of the skin. Tinea cruris is a fungal infection of the groin area, often caused by Trichophyton rubrum. It is characterized by redness, itching, and scaling of the skin. Both conditions are caused by a fungus that thrives in warm, moist environments. They are often spread by direct contact with an infected person or animal, or by indirect contact with contaminated objects such as towels, shoes, or clothing. The infection is usually self-limiting and can be treated with topical antifungal medications. In severe cases, oral antifungal medications may be necessary. Prevention involves keeping the affected area clean and dry, avoiding sharing personal items, and wearing clean, dry clothing.
