

Epidermoid Cyst is a non-infectious, slow-growing, cystic lesion of the skin, typically found on the face, neck, and scalp. It is a type of inclusion cyst, where the cyst is lined by stratified squamous epithelium and contains keratinous material. The cyst is usually painless and can be removed surgically if it becomes bothersome or infected. The cyst is often found in the dermis, and its growth is slow and painless. The cyst is often found in the dermis, and its growth is slow and painless. The cyst is often found in the dermis, and its growth is slow and painless.
