

ERYTHRASMA: A skin condition caused by the bacterium Corynebacterium minutissimum. It is characterized by red, scaly patches that often appear in the folds of the skin, such as the armpits, groin, and between the toes. The patches are usually asymptomatic but can be itchy. Erythrasma is often confused with tinea (fungal infection) and psoriasis. It is diagnosed using a Wood's lamp, which causes the affected areas to glow coral-red. Treatment typically involves topical antibiotics or antifungals.
