

Ingrown toenails are a common condition that can be caused by a variety of factors, including trauma, infection, and poor nail hygiene. The condition is characterized by the nail growing into the surrounding skin, which can cause pain, swelling, and infection. Treatment options include conservative measures such as soaking the foot in warm water, using over-the-counter pain relievers, and keeping the nail clean and dry. In more severe cases, medical intervention may be necessary, such as the removal of the nail or the use of antibiotics to treat the infection.
