

Exostosis is a benign tumor of the bone, usually composed of cartilage. It is characterized by a bony growth on the surface of the bone. The growth is usually painless and slow-growing. It can be found on any part of the body, but is most common on the ribs, scapula, and long bones of the arms and legs. The growth is usually removed by surgery, but it can also be treated with medication. The growth is usually painless and slow-growing.
